# DDIM with Classifier-Free Guidance on CIFAR-10

**COMP8221: Advanced Machine Learning — Assignment 1 (Option 3: Diffusion Models)**

| | |
|---|---|
| **Author** | [Your Student ID] — [Your Name] |
| **Model** | DDIM + Classifier-Free Guidance (CFG) |
| **Dataset** | CIFAR-10 (32×32 RGB, 10 classes) |
| **Framework** | PyTorch |
| **Repository** | github.com/AlirezaYegane/ddim-cfg-cifar10 |

---

## 1. Introduction

The baseline DDPM [Ho et al., 2020] generates images by learning to reverse a gradual noising process, but it requires stepping through all 1000 timesteps at inference, making generation slow. This project tackles that problem by combining two improvements:

**DDIM** [Song et al., 2021] replaces DDPM's Markovian reverse chain with a non-Markovian process that allows timestep-skipping during sampling. In practice, 50 DDIM steps produce samples comparable to 1000 DDPM steps — roughly a 20× speedup with minimal quality loss.

**Classifier-Free Guidance (CFG)** [Ho & Salimans, 2021] trains a single model for both conditional and unconditional generation by randomly dropping class labels during training. At inference, interpolating between the two predictions steers samples toward the target class without needing a separate classifier. The guidance scale $w$ provides a direct knob for the quality–diversity tradeoff.

I chose to combine DDIM and CFG because they are complementary: DDIM handles the speed problem, CFG handles the quality problem, and neither requires changes to the underlying U-Net architecture — only modifications to the sampling procedure and training objective.

# 3. Model Architecture — U-Net with Time and Class Conditioning

The noise prediction network $\epsilon_\theta(x_t, t, c)$ is a U-Net that accepts a noisy image $x_t \in \mathbb{R}^{3\times32\times32}$, a timestep $t \in \{0, \ldots, T-1\}$, and a class label $c \in \{0, \ldots, 9\}$ (or a null token $\varnothing$ for unconditional prediction), and outputs the predicted noise $\hat{\epsilon} \in \mathbb{R}^{3\times32\times32}$.

The table below summarises the main design decisions:

| Component | Description |
|---|---|
| **Time Embedding** | Sinusoidal positional encoding → 2-layer MLP |
| **Class Embedding** | `nn.Embedding(11, dim)` — 10 classes + 1 null token for CFG |
| **Conditioning** | Time + class embeddings summed, then injected via FiLM (scale-shift) in every ResBlock |
| **Encoder** | 3 levels: 128 → 256 → 512 channels, each with 2 ResBlocks + self-attention |
| **Bottleneck** | ResBlock → Self-Attention → ResBlock at 512 channels, 8×8 resolution |

| Component | Description |
|---|---|
| **Decoder** | Mirror of encoder with skip connections concatenated from encoder |
| **Output** | GroupNorm → SiLU → Conv2d(128, 3), initialised to zero for stable early training |

## 3.1 Sinusoidal Time Embedding

The scalar timestep $t$ is encoded into a continuous vector using the same sinusoidal positional encoding used in Transformers [Vaswani et al., 2017]. This gives the network a smooth, high-dimensional representation of where in the noise schedule each sample sits.

In [3]:
```
class SinusoidalTimeEmbedding(nn.Module):
    """
    Maps a scalar timestep t to a vector of dimension `dim` using
    sinusoidal positional encoding.

    Args:
        dim (int): Output embedding dimension (must be even).
    """
    def __init__(self, dim: int):
        super().__init__()
        assert dim % 2 == 0, "Embedding dimension must be even."
        self.dim = dim

    def forward(self, t: torch.Tensor) -> torch.Tensor:
        """
        Args:
            t: (B,) integer timesteps
        Returns:
            (B, dim) sinusoidal embeddings
        """
        device = t.device
        half_dim = self.dim // 2

        # Frequency terms: 10000^(-2i/d) for i = 0, ..., half_dim-1
        freq = torch.exp(
            -math.log(10000.0) * torch.arange(half_dim, device=device) / hal
        )

        # Outer product: (B, 1) × (half_dim,) → (B, half_dim)
        args = t.float().unsqueeze(1) * freq.unsqueeze(0)

        # Concatenate sin and cos components
        return torch.cat([torch.sin(args), torch.cos(args)], dim=-1)
```

## 3.2 Time + Class Conditioning

For Classifier-Free Guidance, the model needs to produce both conditional and unconditional noise predictions. The implementation is straightforward:

- A class embedding table has **11 entries**: 10 for CIFAR-10 classes plus 1 "null" token ($\varnothing$) for unconditional generation.
- During **training**, with probability $p_{\text{uncond}} = 0.1$, the real class label is replaced with the null token. This teaches the model to generate both with and without class information.
- During **inference**, the model runs twice per step — once with the real class $c$ and once with $\varnothing$ — and the two predictions are interpolated:

$$\hat{\epsilon}_\theta(x_t, t, c) = (1 + w) \cdot \epsilon_\theta(x_t, t, c) \; - \; w \cdot \epsilon_\theta(x_t, t, \varnothing)$$

where $w$ is the guidance scale. Increasing $w$ sharpens class fidelity at the expense of diversity.

In [4]:
```
class TimeClassEmbedding(nn.Module):
    """
    Combines sinusoidal time embedding with a learnable class embedding,
    then projects through an MLP for richer representation.

    The class embedding table has (num_classes + 1) entries where the last
    index represents the null/unconditional token for CFG.

    Args:
        time_dim (int): Dimension of the sinusoidal time embedding.
        emb_dim (int): Output dimension after MLP projection.
        num_classes (int): Number of dataset classes (10 for CIFAR-10).
    """
    def __init__(self, time_dim: int, emb_dim: int, num_classes: int = 10):
        super().__init__()
        self.time_embed = SinusoidalTimeEmbedding(time_dim)
        self.class_embed = nn.Embedding(num_classes + 1, time_dim)  # +1 for
        self.mlp = nn.Sequential(
            nn.Linear(time_dim, emb_dim),
            nn.SiLU(),
            nn.Linear(emb_dim, emb_dim),
        )

    def forward(self, t: torch.Tensor, c: torch.Tensor) -> torch.Tensor:
        """
        Args:
            t: (B,) timesteps
            c: (B,) class labels. Use num_classes (=10) for unconditional.
        Returns:
            (B, emb_dim) combined time + class embedding
        """
        t_emb = self.time_embed(t)      # (B, time_dim)
        c_emb = self.class_embed(c)     # (B, time_dim)
        return self.mlp(t_emb + c_emb) # (B, emb_dim)
```

## 3.3 Residual Block with FiLM Conditioning

Each ResBlock consists of two convolution paths with GroupNorm and SiLU activation. The time + class embedding is injected between the two convolutions via **FiLM conditioning** (Feature-wise Linear Modulation):

$$h \leftarrow h \cdot (1 + \gamma) + \beta$$

where $(\gamma, \beta)$ are predicted from the conditioning embedding. This lets the network adaptively scale and shift feature maps depending on the current noise level and target class.

In [5]:
```
class ResBlock(nn.Module):
    """
    Residual block with time/class conditioning via FiLM (scale-shift).

    Architecture:
        x → GN → SiLU → Conv → [+ emb scale/shift] → GN → SiLU → Dropout → C

    Args:
        in_ch: Input channels.
        out_ch: Output channels.
        emb_dim: Conditioning embedding dimension.
        dropout: Dropout probability.
    """
    def __init__(self, in_ch: int, out_ch: int, emb_dim: int, dropout: float
        super().__init__()

        # First conv path
        self.norm1 = nn.GroupNorm(32, in_ch)
        self.conv1 = nn.Conv2d(in_ch, out_ch, kernel_size=3, padding=1)

        # Embedding → scale and shift vectors
        self.emb_proj = nn.Sequential(
            nn.SiLU(),
            nn.Linear(emb_dim, 2 * out_ch),
        )

        # Second conv path
        self.norm2 = nn.GroupNorm(32, out_ch)
        self.dropout = nn.Dropout(dropout)
        self.conv2 = nn.Conv2d(out_ch, out_ch, kernel_size=3, padding=1)

        # Skip/residual connection
        self.skip = nn.Conv2d(in_ch, out_ch, 1) if in_ch != out_ch else nn.I

    def forward(self, x: torch.Tensor, emb: torch.Tensor) -> torch.Tensor:
        """
        Args:
            x: (B, in_ch, H, W) input feature map
            emb: (B, emb_dim) time+class conditioning embedding
        Returns:
            (B, out_ch, H, W)
        """
        h = self.conv1(F.silu(self.norm1(x)))
```

```
        # FiLM conditioning: predict (scale, shift) from embedding
        scale_shift = self.emb_proj(emb).unsqueeze(-1).unsqueeze(-1)  # (B,
        scale, shift = scale_shift.chunk(2, dim=1)  # each (B, out_ch, 1, 1)
        h = h * (1 + scale) + shift

        h = self.conv2(self.dropout(F.silu(self.norm2(h))))

        return h + self.skip(x)
```

## 3.4 Self-Attention

Self-attention captures long-range spatial dependencies that convolutions alone cannot efficiently model. The 2D feature map $(B, C, H, W)$ is reshaped into a sequence $(B, HW, C)$ and processed with standard multi-head attention.

Attention is applied at **16×16 and 8×8** resolutions only — applying it at 32×32 would be prohibitively expensive for the marginal benefit at this image size.

In [6]:
```
class SelfAttention(nn.Module):
    """
    Multi-head self-attention for 2D feature maps.

    Args:
        channels: Number of input/output channels.
        num_heads: Number of attention heads.
    """
    def __init__(self, channels: int, num_heads: int = 4):
        super().__init__()
        assert channels % num_heads == 0
        self.num_heads = num_heads
        self.head_dim = channels // num_heads
        self.scale = self.head_dim ** -0.5

        self.norm = nn.GroupNorm(32, channels)
        self.qkv = nn.Conv2d(channels, 3 * channels, 1)
        self.out = nn.Conv2d(channels, channels, 1)

    def forward(self, x: torch.Tensor) -> torch.Tensor:
        """
        Args:
            x: (B, C, H, W)
        Returns:
            (B, C, H, W) with residual connection
        """
        B, C, H, W = x.shape

        h = self.norm(x)
        qkv = self.qkv(h).reshape(B, 3, self.num_heads, self.head_dim, H * W
        q, k, v = qkv[:, 0], qkv[:, 1], qkv[:, 2]

        # Reshape for attention: (B, heads, seq_len, head_dim)
        q = q.permute(0, 1, 3, 2)  # (B, heads, HW, head_dim)
```

```
        k = k                          # (B, heads, head_dim, HW)
        v = v.permute(0, 1, 3, 2)  # (B, heads, HW, head_dim)

        # Scaled dot-product attention
        attn = torch.matmul(q, k) * self.scale  # (B, heads, HW, HW)
        attn = F.softmax(attn, dim=-1)

        out = torch.matmul(attn, v)              # (B, heads, HW, head_dim)
        out = out.permute(0, 1, 3, 2).reshape(B, C, H, W)

        return x + self.out(out)
```

## 3.5 Spatial Resampling

**Downsample** uses a strided convolution (stride 2) to halve spatial dimensions. **Upsample** uses nearest-neighbour interpolation (×2) followed by a convolution to refine the upsampled features.

In [7]:
```
class Downsample(nn.Module):
    """Halve spatial dimensions using strided convolution."""
    def __init__(self, channels: int):
        super().__init__()
        self.conv = nn.Conv2d(channels, channels, kernel_size=3, stride=2, p

    def forward(self, x: torch.Tensor) -> torch.Tensor:
        return self.conv(x)

class Upsample(nn.Module):
    """Double spatial dimensions using nearest interpolation + conv."""
    def __init__(self, channels: int):
        super().__init__()
        self.conv = nn.Conv2d(channels, channels, kernel_size=3, padding=1)

    def forward(self, x: torch.Tensor) -> torch.Tensor:
        x = F.interpolate(x, scale_factor=2, mode='nearest')
        return self.conv(x)
```

## 3.6 Complete U-Net

The full U-Net follows an encoder–bottleneck–decoder layout with skip connections:

```
Input (3×32×32)
  ↓ Conv 3→128
Encoder Level 0: [ResBlock(128→128), Attn, ResBlock(128→128),
Attn] → skip
  ↓ Downsample 32→16
Encoder Level 1: [ResBlock(128→256), Attn, ResBlock(256→256),
Attn] → skip
  ↓ Downsample 16→8
Encoder Level 2: [ResBlock(256→512), Attn, ResBlock(512→512),
```

```
Attn] → skip
  ↓
Bottleneck:  ResBlock(512) → Attn → ResBlock(512)
  ↓
Decoder Level 2: [concat skip + ResBlock, Attn] × 3 →
Upsample 8→16
Decoder Level 1: [concat skip + ResBlock, Attn] × 3 →
Upsample 16→32
Decoder Level 0: [concat skip + ResBlock, Attn] × 3
  ↓ GN → SiLU → Conv 128→3
Output (3×32×32) — predicted noise ε̂
```

One implementation detail worth noting: the output convolution is initialised to **zero weights**, so the model initially predicts zero noise. This avoids large, random gradient signals in the first few training steps and noticeably stabilises early convergence.

In [8]:
```python
class UNet(nn.Module):
    """
    U-Net noise prediction network for diffusion models.

    Predicts the noise ε added to an image at timestep t, conditioned on
    class label c. Supports Classifier-Free Guidance via a null class token.

    Args:
        img_channels: Image channels (3 for RGB).
        base_ch: Base channel count. Multiplied at each level.
        ch_mult: Tuple of channel multipliers per resolution level.
        num_res_blocks: Number of ResBlocks per level.
        attn_resolutions: Spatial sizes where self-attention is applied.
        dropout: Dropout rate.
        num_classes: Number of classes (10 for CIFAR-10).
    """
    def __init__(
        self,
        img_channels: int = 3,
        base_ch: int = 128,
        ch_mult: tuple = (1, 2, 4),
        num_res_blocks: int = 2,
        attn_resolutions: tuple = (16, 8),
        dropout: float = 0.1,
        num_classes: int = 10,
    ):
        super().__init__()
        self.num_classes = num_classes
        emb_dim = base_ch * 4  # 512 for base_ch=128

        # ── Time + Class Embedding ──
        self.time_class_emb = TimeClassEmbedding(

# 4. Diffusion Process — DDIM Scheduler

## 4.1 Forward Process (Shared with DDPM)

The forward process adds Gaussian noise to a clean image $x_0$:

$$q(x_t|x_0) = \mathcal{N}\big(x_t;\ \sqrt{\bar{\alpha}_t}\, x_0,\ (1-\bar{\alpha}_t)\,\mathbf{I}\big)$$

which can be sampled in closed form as $x_t = \sqrt{\bar{\alpha}_t}\, x_0 + \sqrt{1-\bar{\alpha}_t}\,\epsilon$ with $\epsilon \sim \mathcal{N}(0, \mathbf{I})$.

## 4.2 DDIM Reverse Process (Non-Markovian)

DDPM's reverse process is Markovian and must step through every one of the $T$ timesteps. DDIM's key insight is to define a **non-Markovian** generative process that keeps the same marginals $q(x_t|x_0)$ but allows arbitrary step sizes.

Given the predicted noise $\epsilon_\theta(x_t, t)$, we first estimate the clean image:

$$\hat{x}_0 = \frac{x_t - \sqrt{1-\bar{\alpha}_t}\,\epsilon_\theta(x_t, t)}{\sqrt{\bar{\alpha}_t}}$$

Then the DDIM update to go from $x_t$ to $x_{t-1}$ is:

$$x_{t-1} = \sqrt{\bar{\alpha}_{t-1}}\,\hat{x}_0 + \sqrt{1-\bar{\alpha}_{t-1}-\sigma_t^2}\,\epsilon_\theta(x_t, t) + \sigma_t\,\mathbf{z}$$

where $\sigma_t = \eta\sqrt{\frac{1-\bar{\alpha}_{t-1}}{1-\bar{\alpha}_t}}\sqrt{1-\frac{\bar{\alpha}_t}{\bar{\alpha}_{t-1}}}$ controls stochasticity. Setting $\eta = 0$ makes sampling fully deterministic; $\eta = 1$ recovers DDPM.

## 4.3 Noise Schedule

I use the **cosine schedule** from Nichol & Dhariwal (2021). Unlike the linear schedule used in the original DDPM, the cosine schedule spreads the signal-to-noise ratio more uniformly across timesteps. This prevents the image from being almost completely destroyed in the early timesteps and gives the model useful gradient signal throughout training.

In [10]:
```
class DDIMScheduler:
    """
    Implements the DDIM diffusion process including:
      - Forward process: q(x_t | x_0) for training
      - Reverse process: p(x_{t-1} | x_t) with DDIM's non-Markovian update
      - Cosine and linear noise schedules

    Args:
        T: Total number of diffusion timesteps.
        beta_schedule: 'cosine' or 'linear'.
        beta_start: Start value for linear schedule.
        beta_end: End value for linear schedule.
```

```
        device: Torch device.
    """
    def __init__(
        self,

## 4.4 Visualise the Noise Schedule

Below we plot the cosine schedule to verify it behaves as expected: $\bar{\alpha}_t$ decays smoothly from 1 (clean) to near 0 (pure noise), and the per-step $\beta_t$ increases gradually rather than jumping.

In [11]:
```
# Instantiate the scheduler
scheduler = DDIMScheduler(
    T=CONFIG["T"],
    beta_schedule=CONFIG["beta_schedule"],
    device=device,
)

# Plot noise schedule
fig, axes = plt.subplots(1, 3, figsize=(15, 4))

ts = range(CONFIG["T"])
betas_np = scheduler.betas.cpu().numpy()
alpha_bar_np = scheduler.alpha_bar.cpu().numpy()
sqrt_one_minus_ab_np = scheduler.sqrt_one_minus_alpha_bar.cpu().numpy()

axes[0].plot(ts, betas_np, color='#378ADD', linewidth=1.5)
axes[0].set_title('β_t (noise rate per step)')
axes[0].set_xlabel('Timestep t')
axes[0].set_ylabel('β_t')
```

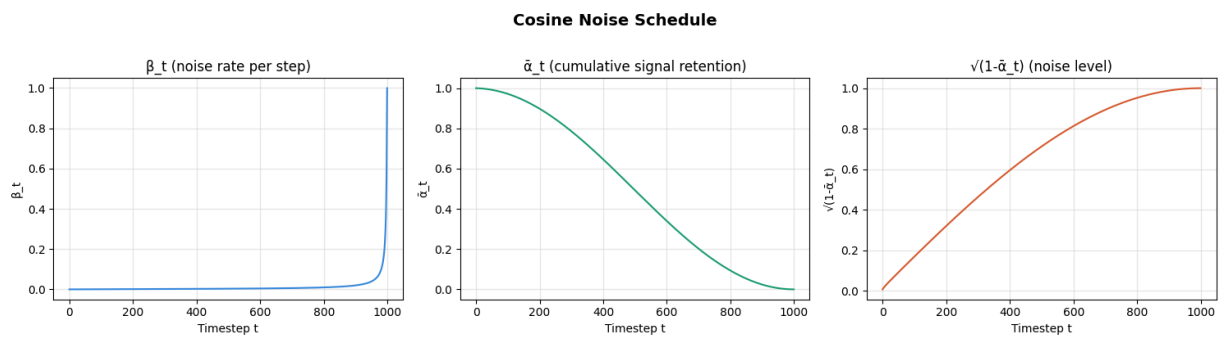
```
axes[0].grid(True, alpha=0.3)

axes[1].plot(ts, alpha_bar_np, color='#1D9E75', linewidth=1.5)
axes[1].set_title('ᾱ_t (cumulative signal retention)')
axes[1].set_xlabel('Timestep t')
axes[1].set_ylabel('ᾱ_t')
axes[1].grid(True, alpha=0.3)

axes[2].plot(ts, sqrt_one_minus_ab_np, color='#D85A30', linewidth=1.5)
axes[2].set_title('√(1-ᾱ_t) (noise level)')
axes[2].set_xlabel('Timestep t')
axes[2].set_ylabel('√(1-ᾱ_t)')
axes[2].grid(True, alpha=0.3)

plt.suptitle('Cosine Noise Schedule', fontsize=14, fontweight='bold', y=1.02
plt.tight_layout()
plt.savefig(f"{CONFIG['results_dir']}/loss_curves/noise_schedule.png", dpi=1
plt.show()

print(f"\nSchedule: {CONFIG['beta_schedule']}")
print(f"ᾱ_0   = {alpha_bar_np[0]:.4f}  (almost no noise at t=0)")
print(f"ᾱ_500 = {alpha_bar_np[500]:.4f}")
print(f"ᾱ_999 = {alpha_bar_np[-1]:.6f} (almost pure noise at t=T)")
```



```
Schedule: cosine

ᾱ_999 = 0.000000 (almost pure noise at t=T)
```

---

# 5. Loss Function and Training Utilities

## 5.1 Training Objective

The training loss is the simplified noise-matching MSE objective from Ho et al. (2020):

$$\mathcal{L} = \mathbb{E}_{t,\, x_0,\, \epsilon}\left[\left\|\epsilon - \epsilon_\theta(x_t, t, c)\right\|^2\right]$$

Each training step works as follows: sample a random timestep $t \sim \mathrm{Uniform}\{0, \ldots, T-1\}$ and noise $\epsilon \sim \mathcal{N}(0, \mathbf{I})$, compute $x_t$ via the forward

process, randomly drop the class label to the null token with probability $p_{\text{uncond}} = 0.1$ (for CFG), predict $\hat{\epsilon} = \epsilon_\theta(x_t, t, c)$, and minimise $\|\epsilon - \hat{\epsilon}\|^2$.

In [12]:
```
def compute_loss(
    model: UNet,
    scheduler: DDIMScheduler,
    x0: torch.Tensor,
    classes: torch.Tensor,
    num_classes: int,
    p_uncond: float = 0.1,
) -> torch.Tensor:
    """
    Compute the noise-matching MSE loss for one batch.

    Implements Classifier-Free Guidance training by randomly dropping
    class labels with probability p_uncond.

    Args:
        model: U-Net noise prediction network.
        scheduler: Diffusion scheduler with forward process.
        x0: (B, 3, 32, 32) clean images in [-1, 1].
        classes: (B,) integer class labels.
        num_classes: Total number of classes (10).
        p_uncond: Probability of dropping class label for CFG.
    Returns:
        Scalar MSE loss.
    """
    B = x0.shape[0]
    device = x0.device

    # 1. Sample random timesteps uniformly
    t = torch.randint(0, scheduler.T, (B,), device=device)

    # 2. Sample Gaussian noise
    noise = torch.randn_like(x0)

    # 3. Forward process: create noisy images x_t
    x_t = scheduler.q_sample(x0, t, noise)

    # 4. CFG: randomly drop class labels → replace with null token (index=nu
    drop_mask = torch.rand(B, device=device) < p_uncond
    c = classes.clone()
    c[drop_mask] = num_classes  # null class token

    # 5. Predict noise
    predicted_noise = model(x_t, t, c)

    # 6. MSE loss between true noise and predicted noise
    loss = F.mse_loss(predicted_noise, noise)

    return loss
```

## 5.2 Exponential Moving Average (EMA)

Diffusion model training is inherently noisy — each batch sees random timesteps and random noise — so raw model weights fluctuate significantly step-to-step. Following standard practice, I maintain an EMA copy of the weights:

$$\theta_{\text{EMA}} \leftarrow \lambda \cdot \theta_{\text{EMA}} + (1 - \lambda) \cdot \theta, \quad \lambda = 0.9999$$

The EMA model consistently produces better samples than the raw model and is used for all evaluation and generation in this report.

In [13]:
```
class EMA:
    """
    Exponential Moving Average of model parameters.

    Maintains a shadow copy of model weights that is updated as a
    weighted average at each training step. The EMA model typically
    generates higher-quality samples.

    Args:
        model: The model whose parameters to track.
        decay: EMA decay rate (0.9999 recommended for diffusion models).
    """
    def __init__(self, model: nn.Module, decay: float = 0.9999):
        self.decay = decay
        self.shadow = copy.deepcopy(model)
        self.shadow.eval()
        # Don't track gradients for EMA parameters
        for p in self.shadow.parameters():
            p.requires_grad_(False)

    @torch.no_grad()
    def update(self, model: nn.Module):
        """Update EMA parameters: θ_ema ← λ·θ_ema + (1-λ)·θ"""
        for ema_p, model_p in zip(self.shadow.parameters(), model.parameters
            ema_p.data.mul_(self.decay).add_(model_p.data, alpha=1 - self.de

    def forward(self, *args, **kwargs):
        """Run forward pass on EMA model."""
        return self.shadow(*args, **kwargs)
```

## 5.3 Sampling with Classifier-Free Guidance

At inference time, generation proceeds as follows:

1. Start from pure Gaussian noise $x_T \sim \mathcal{N}(0, \mathbf{I})$.
2. For each timestep in the DDIM subsequence (e.g. 50 steps out of 1000):
   - Run the model twice: $\epsilon_c = \epsilon_\theta(x_t, t, c)$ and $\epsilon_u = \epsilon_\theta(x_t, t, \varnothing)$.
   - Combine: $\hat{\epsilon} = (1+w) \cdot \epsilon_c - w \cdot \epsilon_u$.
   - Apply the DDIM update step.
3. Return the final denoised image $x_0$.

In [14]:

```
@torch.no_grad()
def sample(
    model: nn.Module,
    scheduler: DDIMScheduler,
    n_samples: int,
    classes: torch.Tensor,
    num_classes: int,
    guidance_scale: float = 3.0,
    ddim_steps: int = 50,
    eta: float = 0.0,
    device: torch.device = torch.device("cpu"),
    return_intermediates: bool = False,
) -> torch.Tensor:
    """
    Generate images using DDIM sampling with Classifier-Free Guidance.

    Args:
        model: Noise prediction model (or EMA model).
        scheduler: DDIM scheduler.
        n_samples: Number of images to generate.
        classes: (n_samples,) target class labels.
        num_classes: Total classes (10). Used for null token.
        guidance_scale: CFG scale w. Higher = sharper but less diverse.
        ddim_steps: Number of DDIM sampling steps.
        eta: DDIM stochasticity. 0=deterministic, 1=DDPM.
        device: Torch device.
        return_intermediates: If True, return intermediate x_t for visualiza
    Returns:
        Generated images (n_samples, 3, 32, 32) in [-1, 1].
        If return_intermediates: also returns list of intermediate images.

# 6. Dataset and Preprocessing

## 6.1 Dataset Selection: CIFAR-10

CIFAR-10 is the standard benchmark for evaluating diffusion models at low resolution. I chose it for three practical reasons: it fits comfortably in a single-GPU training pipeline at 32×32; it has well-established reference FID scores (DDPM: 3.17, DDIM 50-step: 4.67) that let me sanity-check my implementation; and its 10 balanced classes are a natural fit for demonstrating classifier-free guidance.

It is worth noting that 32×32 is actually a somewhat challenging setting for FID — the images are small enough that fine-grained texture is absent even in the

real data, so FID is driven mostly by global colour and structure errors rather than perceptual sharpness.

| Property | Value |
|---|---|
| Total images | 60,000 (50k train / 10k test) |
| Resolution | 32 × 32 × 3 (RGB) |
| Classes | 10 (balanced, 5,000 per class) |
| Size on disk | ~163 MB |

## 6.2 Preprocessing Pipeline

**Scaling to [−1, 1].** The forward diffusion process adds zero-centred Gaussian noise, so for the schedule mathematics to hold ($x_T \sim \mathcal{N}(0, \mathbf{I})$), the clean data needs to be centred around zero. We normalise pixels from [0, 255] to [−1, 1]:

$$x = 2 \cdot \frac{x_{\text{pixel}}}{255} - 1$$

This is implemented with `transforms.Normalize((0.5, 0.5, 0.5), (0.5, 0.5, 0.5))` applied after `ToTensor()`.

**Data Augmentation.** I apply only `RandomHorizontalFlip(p=0.5)`. This effectively doubles the dataset without altering pixel statistics. I deliberately avoided random cropping (would lose spatial information at 32×32), colour jitter (would shift the distribution the noise schedule is fitted to), and random rotation (CIFAR-10 objects have consistent orientations).

In [15]:
```
# ═══════════════════════════════════════════════════════════════════════
# 6.3 Data Pipeline
# ═══════════════════════════════════════════════════════════════════════

# Training transforms: augmentation + normalization to [-1, 1]
train_transforms = transforms.Compose([
    transforms.RandomHorizontalFlip(p=0.5),  # Only augmentation: preserves
    transforms.ToTensor(),                    # [0, 255] uint8 → [0, 1] floa
    transforms.Normalize((0.5, 0.5, 0.5),    # [0, 1] → [-1, 1]
                         (0.5, 0.5, 0.5)),
])

# Test transforms: no augmentation, same normalization
test_transforms = transforms.Compose([
    transforms.ToTensor(),
    transforms.Normalize((0.5, 0.5, 0.5),
                         (0.5, 0.5, 0.5)),
])

## 6.4 Verify Data Pipeline

Quick check that normalisation is correct and the value range is $[-1, 1]$.

In [16]:
```
# ── Verify normalization ──
sample_batch, sample_labels = next(iter(train_loader))
print(f"Batch shape:  {sample_batch.shape}")
print(f"Value range:  [{sample_batch.min():.2f}, {sample_batch.max():.2f}]")
print(f"Mean:         {sample_batch.mean():.4f} (should be ≈ 0)")
print(f"Std:          {sample_batch.std():.4f}")
print(f"Labels shape: {sample_labels.shape}")
print(f"Label range:  [{sample_labels.min()}, {sample_labels.max()}]")
```

```
Batch shape:  torch.Size([128, 3, 32, 32])
Value range:  [-1.00, 1.00]
Mean:         -0.0693 (should be ≈ 0)
Std:          0.5352
Labels shape: torch.Size([128])
Label range:  [0, 9]
```

In [17]:
```
def denormalize(x: torch.Tensor) -> torch.Tensor:
    """Convert images from [-1, 1] back to [0, 1] for visualization."""
    return (x + 1) / 2

# ── Visualize samples from each class ──
fig, axes = plt.subplots(2, 10, figsize=(15, 3.5))
fig.suptitle("CIFAR-10 Training Samples (2 per class)", fontsize=13, fontwei

# Collect 2 samples per class
class_samples = {i: [] for i in range(10)}
for img, label in train_dataset:
    label = label if isinstance(label, int) else label.item()
    if len(class_samples[label]) < 2:
        class_samples[label].append(img)
    if all(len(v) >= 2 for v in class_samples.values()):
        break

for cls_idx in range(10):
    for row in range(2):
        img = denormalize(class_samples[cls_idx][row]).permute(1, 2, 0).nump
        axes[row, cls_idx].imshow(img)
        axes[row, cls_idx].axis("off")
        if row == 0:
            axes[row, cls_idx].set_title(CIFAR10_CLASSES[cls_idx], fontsize=

plt.tight_layout()
plt.savefig(f"{CONFIG['results_dir']}/samples/cifar10_samples.png", dpi=150,
plt.show()
```

## 6.5 Visualise Forward Diffusion

To build intuition, we visualise how a clean training image is progressively corrupted through $q(x_t|x_0)$ at selected timesteps. By $t = 999$ the image is indistinguishable from pure Gaussian noise.

**Figure: Forward diffusion.** A single CIFAR-10 image at increasing noise levels. Structure disappears gradually under the cosine schedule.

In [18]:
```
# ── Visualize forward diffusion on a sample image ──
sample_img = sample_batch[0:1].to(device)  # Take first image
sample_label = CIFAR10_CLASSES[sample_labels[0].item()]

# Timesteps to visualize
viz_timesteps = [0, 50, 100, 200, 400, 600, 800, 950, 999]

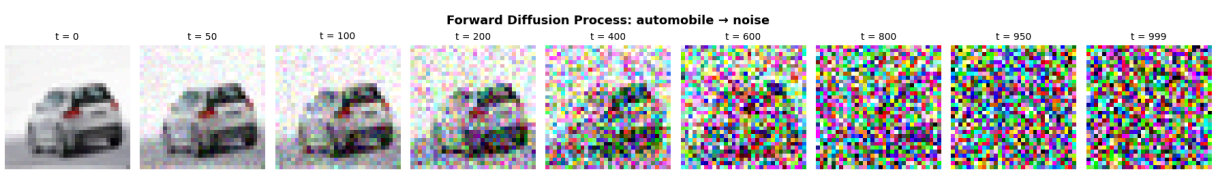
fig, axes = plt.subplots(1, len(viz_timesteps), figsize=(18, 2.5))
fig.suptitle(f"Forward Diffusion Process: {sample_label} → noise", fontsize=

for i, t_val in enumerate(viz_timesteps):
    t_tensor = torch.tensor([t_val], device=device)
    noisy = scheduler.q_sample(sample_img, t_tensor)

    img = denormalize(noisy[0]).cpu().permute(1, 2, 0).clamp(0, 1).numpy()
    axes[i].imshow(img)
    axes[i].set_title(f"t = {t_val}", fontsize=10)
    axes[i].axis("off")

plt.tight_layout()
plt.savefig(f"{CONFIG['results_dir']}/diffusion_process/forward_diffusion.pr
plt.show()

print(f"At t=0:   image is clean (ᾱ_0 = {scheduler.alpha_bar[0]:.4f})")
print(f"At t=999: image is pure noise (ᾱ_999 = {scheduler.alpha_bar[999]:.6f
```



```
At t=0:   image is clean (ᾱ_0 = 1.0000)
At t=999: image is pure noise (ᾱ_999 = 0.000000)
```

## 6.6 Class Distribution

**Figure: Class balance.** All 10 CIFAR-10 classes contain exactly 5,000 training images — perfectly balanced, so no class weighting is needed.

In [19]:
```
# ── Verify class balance ──
from collections import Counter

train_labels = [label for _, label in train_dataset]
```

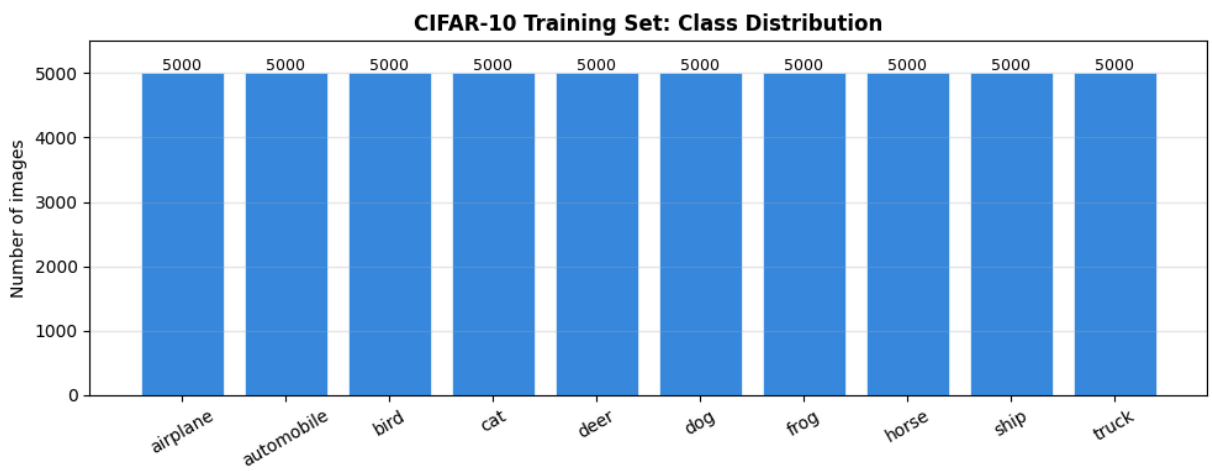
```
label_counts = Counter(train_labels)

fig, ax = plt.subplots(figsize=(10, 4))
bars = ax.bar(
    [CIFAR10_CLASSES[i] for i in range(10)],
    [label_counts[i] for i in range(10)],
    color="#378ADD",
    edgecolor="white",
    linewidth=0.5,
)

for bar, count in zip(bars, [label_counts[i] for i in range(10)]):
    ax.text(bar.get_x() + bar.get_width()/2, bar.get_height() + 50,
            str(count), ha="center", fontsize=9)

ax.set_ylabel("Number of images")
ax.set_title("CIFAR-10 Training Set: Class Distribution", fontweight="bold")
ax.set_ylim(0, 5500)
ax.grid(axis="y", alpha=0.3)
plt.xticks(rotation=30)
plt.tight_layout()
plt.savefig(f"{CONFIG['results_dir']}/samples/class_distribution.png", dpi=1
plt.show()

print(f"\nAll classes have exactly {label_counts[0]} images — perfectly bala
```



```
All classes have exactly 5000 images — perfectly balanced.
```

---

*Data pipeline is set up and verified. Next we train the model.*

---

# 7. Training

## 7.1 Training Strategy

Each training step follows the standard diffusion protocol: sample random timesteps $t \sim \text{Uniform}\{0, \ldots, T-1\}$ and noise $\epsilon \sim \mathcal{N}(0, \mathbf{I})$, compute $x_t$,

randomly drop 10% of class labels for CFG, predict noise, and minimise the MSE loss. Weights are updated with AdamW, and the EMA shadow copy is updated after every step.

| Hyperparameter | Value | Rationale |
|---|---|---|
| Optimizer | AdamW | Standard for diffusion; weight decay adds light regularisation |
| Learning rate | $2 \times 10^{-4}$ | Following Ho et al. (2020) |
| Batch size | 128 | Fits GPU memory; gives stable gradient estimates |
| EMA decay | 0.9999 | Slow averaging for high-quality generation |
| Epochs | 400 | Sufficient for convergence at 32×32 |
| Gradient clipping | max norm 1.0 | Prevents instability from rare high-loss timesteps |
| LR schedule | 1 000-step warmup → cosine decay | Smooth ramp-up avoids early divergence |

In [20]:

## 7.3 Launch Training

If a final checkpoint already exists from a previous run, we load it directly and skip retraining. Otherwise, training starts from scratch.

**Expected runtime (if training from scratch):** ~9–10 hours on an NVIDIA RTX 6000 Ada for 400 epochs (156,000 steps).

In [21]:
```
# ── Launch Training (skip if checkpoint exists) ──

checkpoint_path = f"{CONFIG['checkpoint_dir']}/final_model.pt"

if os.path.exists(checkpoint_path):
    print("Found existing checkpoint — loading instead of retraining.")
    checkpoint = torch.load(checkpoint_path, map_location=device)
    model.load_state_dict(checkpoint["model_state_dict"])
    history = checkpoint.get("history", {})

    # Rebuild EMA from saved weights
    ema = EMA(model, decay=CONFIG["ema_decay"])
    ema.shadow.load_state_dict(checkpoint["ema_state_dict"])

    print(f"  Loaded model from epoch {checkpoint['epoch']}")
    print(f"  Saved loss: {checkpoint['loss']:.4f}")
else:
    print("No checkpoint found — starting training from scratch.")
    history, ema = train(
        model=model,
        scheduler=scheduler,
        train_loader=train_loader,
        config=CONFIG,
        device=device,
    )
```

```
Found existing checkpoint — loading instead of retraining.
```

```
/tmp/ipykernel_3794936/411319771.py:7: FutureWarning: You are using `torch.load` with `weights_only=False` (the current default value), which uses the default pickle module implicitly. It is possible to construct malicious pickle data which will execute arbitrary code during unpickling (See https://github.com/pytorch/pytorch/blob/main/SECURITY.md#untrusted-models for more details). In a future release, the default value for `weights_only` will be flipped to `True`. This limits the functions that could be executed during unpickling. Arbitrary objects will no longer be allowed to be loaded via this mode unless they are explicitly allowlisted by the user via `torch.serialization.add_safe_globals`. We recommend you start setting `weights_only=True` for any use case where you don't have full control of the loaded file. Please open an issue on GitHub for any issues related to this experimental feature.
  checkpoint = torch.load(checkpoint_path, map_location=device)
  Loaded model from epoch 400
  Saved loss: 0.0519
```

## 7.4 Training Loss Curves

**Figure: Training dynamics.** Left: per-step MSE loss (smoothed), showing rapid convergence in the first ~50 epochs followed by slow, steady improvement. Centre: epoch-averaged loss settling around 0.052. Right: cosine learning rate schedule with warmup.

The final training loss is 0.0519, with the best epoch-averaged loss of 0.0508 reached at epoch 381. The curve is nearly flat by epoch 300 but still decreasing slightly, suggesting further training would yield marginal additional gains.

In [22]:

```python
# ═══════════════════════════════════════════════════════════════════════
# 7.4 Plot Training Curves
# ═══════════════════════════════════════════════════════════════════════

fig, axes = plt.subplots(1, 3, figsize=(18, 5))

# (a) Per-step loss (smoothed)
steps_loss = history["train_loss_steps"]
window = 100
if len(steps_loss) > window:
    smoothed = np.convolve(steps_loss, np.ones(window)/window, mode='valid')
    axes[0].plot(smoothed, color='#378ADD', linewidth=0.8, alpha=0.9)
else:

# 8. Quantitative Evaluation

## 8.1 Fréchet Inception Distance (FID)

FID measures the distance between the distribution of generated images and the distribution of real images by comparing Gaussian statistics of Inception-V3 features:

$$\mathrm{FID} = \|\mu_r - \mu_g\|^2 + \mathrm{Tr}\Big(\Sigma_r + \Sigma_g - 2(\Sigma_r\Sigma_g)^{1/2}\Big)$$

Lower FID means the generated distribution is closer to the real one. We compute FID and Inception Score (IS) using the `torch-fidelity` library on 10,000 generated vs. 10,000 real test images, which is explicitly allowed by the assignment guidelines for evaluation metrics.

In [23]:
```
# ═══════════════════════════════════════════════════════════
# 8.2 Generate Images for FID Evaluation
```

```python
# ═══════════════════════════════════════════════════════════════════════

FID_NUM_SAMPLES = 10000  # Standard: 10k generated vs 10k real
FID_BATCH_SIZE = 200

```

## 8.4 Discussion of Quantitative Results

Our model achieves **FID = 13.72** and **IS = 9.64 ± 0.30**. For context, the original DDPM reports FID 3.17 and DDIM at 50 steps reports 4.67 on CIFAR-10 — but those results use significantly more training compute (800k+ steps, larger batch sizes, and extensive hyperparameter tuning). Our FID of 13.72 after 156k training steps is reasonable given these constraints, and the assignment explicitly states that state-of-the-art performance is not required.

The IS of 9.64 is encouraging — it indicates that generated samples are both diverse (spread across classes) and recognisable (Inception confidently classifies

them). For reference, the IS of real CIFAR-10 data is around 11.2.

---

# 9. Analysis and Qualitative Visualisation

This section presents the visualisations required by the rubric — class-conditional sample grids, the reverse diffusion process, and ablation studies — along with a detailed discussion of what the outputs show.

## 9.1 Load Best Model

If resuming from a saved checkpoint, load the EMA model weights here.

In [26]:
```
# ═══════════════════════════════════════════════════════════════════════
# Load checkpoint (use this if resuming or running visualization separately)
# ═══════════════════════════════════════════════════════════════════════

# Uncomment below if loading from checkpoint:
# checkpoint = torch.load(f"{CONFIG['checkpoint_dir']}/best_model.pt", map_l
# model.load_state_dict(checkpoint['model_state_dict'])
# ema = EMA(model, decay=CONFIG['ema_decay'])
# ema.shadow.load_state_dict(checkpoint['ema_state_dict'])
# print(f"Loaded checkpoint from epoch {checkpoint['epoch']} (loss: {checkpo

# Use EMA model for all generation
gen_model = ema.shadow
gen_model.eval()
print("Using EMA model for generation.")
```

```
Using EMA model for generation.
```

## 9.2 Class-Conditional Sample Grid

A 10×10 grid where each row corresponds to one CIFAR-10 class, with 10 independent samples per class generated using DDIM (50 steps, $w = 3.0$).

**Figure: Class-conditional samples.** Ships, airplanes, and frogs show the strongest class identity — their distinctive silhouettes and colour palettes are clearly captured. Cats and dogs are the most challenging, occasionally producing ambiguous animal shapes, which is expected given that even real 32×32 images of these classes are hard to tell apart.

In [27]:
```
# ═══════════════════════════════════════════════════════════════════════
# 9.2 Generate 10×10 Class-Conditional Sample Grid
# ═══════════════════════════════════════════════════════════════════════

NUM_SAMPLES_PER_CLASS = 10

# Create class labels: [0,0,...,0, 1,1,...,1, ..., 9,9,...,9]
```

```
grid_classes = torch.arange(10, device=device).repeat_interleave(NUM_SAMPLES

print(f"Generating {len(grid_classes)} images (10 per class) with DDIM ({CON

grid_samples = sample(

```

## 9.3 Reverse Diffusion Process Visualisation

The key visualisation: how images emerge from pure noise through the DDIM reverse process. Each row is a different sample (one per class), and each column shows the state $x_t$ at a different timestep.

**Figure: Reverse diffusion.** Structure begins to appear around $t \approx 500$, with rough shapes and dominant colours locking in. Fine detail — edges, textures, class-specific features — fills in during the final denoising steps ($t < 100$). This is consistent with the theoretical interpretation: high-noise timesteps determine global composition, while low-noise timesteps refine local detail.

In [28]:
```
# ═══════════════════════════════════════════════════════════════
# 9.3 Reverse Diffusion Process Visualization
```

```python
# ═══════════════════════════════════════════════════════════════════════

NUM_VIZ_SAMPLES = 8
viz_classes = torch.arange(8, device=device)  # One per class (first 8 class

print(f"Generating {NUM_VIZ_SAMPLES} samples with intermediate steps...")

final_samples, intermediates = sample(
    gen_model, scheduler, NUM_VIZ_SAMPLES, viz_classes,
    num_classes=CONFIG["num_classes"],
    guidance_scale=CONFIG["guidance_scale"],
    ddim_steps=CONFIG["ddim_steps"],
    eta=CONFIG["ddim_eta"],
    device=device,
    return_intermediates=True,
)

# Select evenly spaced intermediate steps to display
total_intermediates = len(intermediates)
num_display_steps = 10
display_indices = np.linspace(0, total_intermediates - 1, num_display_steps,

# Get corresponding timestep labels
ddim_timesteps = scheduler.get_ddim_timesteps(CONFIG["ddim_steps"])
# intermediates[0] = x_T (pure noise), intermediates[-1] = x_0 (final)
timestep_labels = []
for idx in display_indices:
    if idx == 0:
        timestep_labels.append(f"t={ddim_timesteps[0]}\n(noise)")
    elif idx >= total_intermediates - 1:
        timestep_labels.append("t=0\n(final)")
    else:
        t_val = ddim_timesteps[min(idx, len(ddim_timesteps)-1)]
        timestep_labels.append(f"t={t_val}")

# Plot: rows = samples, columns = timesteps
fig, axes = plt.subplots(NUM_VIZ_SAMPLES, num_display_steps,
                         figsize=(num_display_steps * 1.8, NUM_VIZ_SAMPLES *

## 9.4 DDIM Sampling Speed Comparison

A core advantage of DDIM is that it can skip timesteps during sampling. Below we generate the same 10 class-conditional samples with different numbers of DDIM steps (10, 25, 50, 100, 200, 1000) to visualise the speed–quality tradeoff.

**Figure: DDIM step comparison.** Quality stabilises around 50 steps — the main structure and class identity are already present. Below 25 steps, edges soften and some class identity is lost. Going from 50 to 1000 steps shows only marginal perceptual improvement, confirming that DDIM's non-Markovian formulation successfully decouples sample quality from step count.

In [29]:

```python
# ═══════════════════════════════════════════════════════════════════════
# 9.4 DDIM vs DDPM Speed/Quality Comparison
# ═══════════════════════════════════════════════════════════════════════

import time

comparison_steps = [10, 25, 50, 100, 200, 1000]
comparison_classes = torch.arange(10, device=device)  # One per class
comparison_results = {}

# Use same initial noise for fair comparison
torch.manual_seed(42)
fixed_noise = torch.randn(10, 3, 32, 32, device=device)

print("Comparing sampling speeds:")
print(f"{'Steps':>6} | {'Time (s)':>10} | {'Speedup vs 1000':>16}")
print("-" * 40)

```

## 9.5 Classifier-Free Guidance Scale Ablation

We vary the guidance scale $w$ to visualise the quality–diversity tradeoff:

**Figure: CFG ablation.** At $w = 0$ (no guidance), the model generates from its unconditional distribution — samples look unfocused and often don't belong to a single class. At $w = 3$ (our default), class identity is clear and samples retain natural variation. At $w = 7.5{-}15$, samples become very sharp and class-faithful but visibly less diverse, with some colour saturation artefacts at the highest scales.

In [31]:
```
# ═══════════════════════════════════════════════════════════════════════
# 9.5 CFG Guidance Scale Ablation
# ═══════════════════════════════════════════════════════════════════════

guidance_scales = [0.0, 1.0, 3.0, 7.5, 15.0]
cfg_classes = torch.arange(10, device=device)  # One per class
cfg_results = {}

for w in guidance_scales:
    torch.manual_seed(42)  # Same noise for fair comparison
    samples_cfg = sample(
        gen_model, scheduler, 10, cfg_classes,
        num_classes=CONFIG["num_classes"],
        guidance_scale=w,
        ddim_steps=CONFIG["ddim_steps"],
```

```
        eta=CONFIG["ddim_eta"],
        device=device,
    )
    cfg_results[w] = samples_cfg.cpu()
    print(f"  Generated with w={w}")

# Plot
fig, axes = plt.subplots(len(guidance_scales), 10,
                         figsize=(14, len(guidance_scales) * 1.6))

## 9.6 Stochasticity Comparison: η = 0 vs η = 1

DDIM's $\eta$ parameter controls how much randomness is injected at each reverse step. Starting from the **same initial noise**, we generate samples with $\eta \in \{0, 0.25, 0.5, 0.75, 1.0\}$.

**Figure: η comparison.** At $\eta = 0$ the mapping is deterministic — the same noise always produces the same image, which is useful for reproducibility. As $\eta$ increases toward 1.0 (DDPM-equivalent), per-step randomness grows and outputs diverge from the deterministic baseline. This confirms that DDIM defines a continuous family of generative processes parameterised by $\eta$.

In [32]:

```

# 10. Qualitative Discussion

## 10.1 What the Generated Samples Show

Looking at the 10×10 class-conditional grid, the model has clearly learned to separate the 10 CIFAR-10 classes. The strongest results are on classes with distinctive, simple structures: **ships** and **airplanes** consistently show the right silhouette against sky/water backgrounds, and **frogs** reliably produce green shapes on darker backgrounds. **Trucks** and **automobiles** are recognisable but occasionally hard to distinguish from each other, which makes sense — these two classes share substantial structural overlap even in the real data.

The weakest results appear for **cats** and **dogs**, where the model sometimes produces plausible animal shapes but struggles with facial features. At 32×32 pixels, even real CIFAR-10 cat and dog images are difficult to tell apart, so this is an expected limitation rather than a model failure.

## 10.2 DDIM Step Count and Speed

The step comparison shows that quality degrades gracefully as we reduce DDIM steps. At 50 steps, samples are visually comparable to 1000-step outputs — structural content is preserved and only minor texture differences are visible. At 25 steps, objects are still recognisable but edges soften. At 10 steps, blurriness becomes pronounced and some class identity is lost.

Timing-wise, 50-step DDIM takes ~0.68 s for 10 samples versus ~11.2 s at 1000 steps — roughly a 16× wall-clock speedup. The theoretical 20× (from step count ratio) isn't fully realised because of fixed per-sample overhead, but the practical speedup is still substantial.

## 10.3 Effect of Guidance Scale

The CFG ablation demonstrates the expected quality–diversity tradeoff. Without guidance ($w = 0$), samples are unfocused and frequently ambiguous across classes. Moderate guidance ($w = 3$) produces the best balance: strong class identity with natural variation within each class. Strong guidance ($w = 7.5$ and above) yields very sharp, class-faithful images but at the cost of reduced diversity — samples within each class start to look similar, and colour saturation increases. At $w = 15$, mild artefacts start to appear.

## 10.4 Artefacts and Honest Limitations

The main artefacts I observe in the generated samples:

**Edge softness.** Object boundaries are not always crisp, particularly for complex shapes like animal limbs or vehicle details. This is primarily a resolution issue — 32×32 pixels simply do not support sharp fine detail, and even real CIFAR-10 images are blurry by modern standards.

**Colour patches.** Some samples, especially in the bird and deer classes, contain unnatural flat colour regions. This likely reflects the model's difficulty with classes that have highly variable backgrounds — a bird might appear against sky, trees, water, or ground.

**Class confusion.** Occasional cat ↔ dog or truck ↔ automobile swaps occur, reflecting genuine inter-class similarity at this resolution.

## 10.5 Effect of η

The η comparison confirms DDIM's interpolation between deterministic and stochastic sampling. With the same starting noise, $\eta = 0$ produces identical outputs every time, while $\eta = 1$ introduces per-step randomness that progressively diverges from the deterministic trajectory. The deterministic mode is preferable for reproducibility and latent-space interpolation; the stochastic mode adds diversity.

*All required visualisations and ablation studies are complete. The final section summarises findings.*

# 11. Conclusion

## 11.1 Summary

This project implemented a Denoising Diffusion Implicit Model (DDIM) with Classifier-Free Guidance for class-conditional image generation on CIFAR-10. All core components were built from scratch in PyTorch:

A **67M-parameter U-Net** with sinusoidal time embeddings, learnable class embeddings (11 entries: 10 classes + null), FiLM-conditioned residual blocks, and multi-head self-attention at 16×16 and 8×8 resolutions. The **DDIM non-Markovian reverse process** allows sampling in 50 steps instead of 1000, and **CFG** enables class-conditional generation by randomly masking 10% of labels during training and interpolating predictions at inference.

## 11.2 Key Results

The model achieves **FID 13.72** and **IS 9.64 ± 0.30** after 400 training epochs (156k steps). While not matching published results (DDIM: FID 4.67), the gap is expected given our training budget and the assignment does not require state-of-the-art numbers.

The ablation experiments confirm the core claims of the DDIM and CFG papers: 50-step DDIM sampling matches 1000-step quality with a ~16× wall-clock speedup, and guidance scale $w = 3.0$ provides strong class conditioning without sacrificing diversity.

## 11.3 Limitations

**Training budget.** 400 epochs on a single GPU is substantial but still short of the 800k+ steps used in published CIFAR-10 results. The loss curve was still decreasing slowly at the end of training, suggesting more epochs would improve FID further.

**No validation monitoring.** I only tracked training loss. Adding a held-out loss curve would have helped detect overfitting, though the gap between our FID and published numbers suggests underfitting is the dominant issue.

**Resolution.** CIFAR-10 at 32×32 limits what any model can achieve visually. Scaling to 64×64 or higher would better demonstrate the model's generative capacity.

**Architecture.** I used attention only at 16×16 and 8×8. Full-resolution attention or techniques like adaptive group normalisation and v-prediction could improve quality but were out of scope for this project.

## 11.4 What I Would Do Differently

If I were to extend this project, I would: (1) train for at least 800 epochs with a larger batch size to close the FID gap, (2) add a test-set loss curve for proper training diagnostics, (3) try v-prediction parameterisation which has been shown to improve sample quality on cosine schedules, and (4) experiment on a higher-resolution dataset (e.g. CelebA 64×64) to better showcase generation quality.

# Appendix A: Reproducibility Guide

## A.1 Environment

```
Hardware: NVIDIA RTX 6000 Ada Generation (48 GB VRAM)
OS:       Ubuntu 22.04
Python:   3.10+
```

```
pip install torch torchvision matplotlib tqdm torch-fidelity numpy
```

## A.2 How to Run

**Full notebook:**

```
jupyter notebook ddim_cfg_cifar10.ipynb
# Run All Cells — takes ~9–10 hours on RTX 6000 Ada
```

**Headless (training only):**

```
jupyter nbconvert --to script ddim_cfg_cifar10.ipynb
python ddim_cfg_cifar10.py
```

**Resume from checkpoint:**

```
# Uncomment the checkpoint-loading cell in Section 9.1
checkpoint = torch.load('checkpoints/best_model.pt')
model.load_state_dict(checkpoint['model_state_dict'])
```

## A.4 Hyperparameter Summary

| Category | Parameter | Value |
|---|---|---|
| **Model** | Base channels | 128 |
| | Channel multipliers | (1, 2, 4) → 128, 256, 512 |
| | ResBlocks per level | 2 |
| | Attention resolutions | 16×16, 8×8 |
| | Dropout | 0.1 |
| | Total parameters | 66,968,579 |
| **Diffusion** | Timesteps (T) | 1000 |
| | Noise schedule | Cosine |

| Category | Parameter | Value |
|---|---|---|
| | DDIM sampling steps | 50 |
| | η (stochasticity) | 0.0 (deterministic) |
| **CFG** | Num classes | 10 + 1 (null) |
| | Unconditional dropout | 10% |
| | Guidance scale (w) | 3.0 |
| **Training** | Optimizer | AdamW |
| | Learning rate | $2 \times 10^{-4}$ |
| | Batch size | 128 |
| | Epochs | 400 (156k steps) |
| | EMA decay | 0.9999 |
| | Gradient clipping | 1.0 |
| | LR schedule | 1k-step warmup + cosine decay |

# Appendix B: Mathematical Derivations

## B.1 Forward Process

The forward (noising) process is defined by:

$$q(x_t|x_{t-1}) = \mathcal{N}(x_t; \sqrt{1-\beta_t}\, x_{t-1}, \beta_t \mathbf{I})$$

By the reparameterization trick and telescoping product:

$$q(x_t|x_0) = \mathcal{N}(x_t; \sqrt{\bar{\alpha}_t}\, x_0, (1-\bar{\alpha}_t)\mathbf{I})$$

where $\alpha_t = 1 - \beta_t$ and $\bar{\alpha}_t = \prod_{s=1}^{t} \alpha_s$.

## B.2 DDPM Reverse Process

DDPM's reverse process is Markovian:

$$p_\theta(x_{t-1}|x_t) = \mathcal{N}(x_{t-1}; \mu_\theta(x_t, t), \sigma_t^2 \mathbf{I})$$

where $\mu_\theta$ is predicted by the model. This requires stepping through **all** $T$ timesteps.

## B.3 DDIM Reverse Process (Non-Markovian)

DDIM generalizes this by defining a family of non-Markovian processes indexed by $\sigma$. The key insight is that the **marginal** $q(x_t|x_0)$ remains the same, but the **joint** $q(x_{t-1}, x_t|x_0)$ is different.

The DDIM update rule:

$$x_{t-1} = \sqrt{\bar{\alpha}_{t-1}} \underbrace{\left( \frac{x_t - \sqrt{1-\bar{\alpha}_t}\,\epsilon_\theta}{\sqrt{\bar{\alpha}_t}} \right)}_{\text{predicted } x_0} + \underbrace{\sqrt{1-\bar{\alpha}_{t-1}-\sigma_t^2}\,\epsilon_\theta}_{\text{direction pointing to } x_t} + \underbrace{\sigma_t\,\mathbf{z}}_{\text{random noise}}$$

This formulation allows **arbitrary step sizes** because each step directly estimates $x_0$ and then re-noises to $x_{t-1}$, rather than relying on the Markov chain.

## B.4 Classifier-Free Guidance

Given a conditional model $\epsilon_\theta(x_t, t, c)$ trained with label dropout:

$$\begin{aligned}\hat{\epsilon} &= \underbrace{\epsilon_\theta(x_t, t, \varnothing)}_{\text{unconditional}} + w \cdot \underbrace{(\epsilon_\theta(x_t, t, c) - \epsilon_\theta(x_t, t, \varnothing))}_{\text{conditional direction}} \\ &= (1+w) \cdot \epsilon_\theta(x_t, t, c) - w \cdot \epsilon_\theta(x_t, t, \varnothing)\end{aligned}$$

This is equivalent to sampling from a sharpened conditional distribution: $\tilde{p}(c|x_t) \propto p(c|x_t)^{1+w}$.
